

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

crystalline rocks of the Atlantic coast, but never before from Pennsylvania. The particular locality discovered by Mr. Dailey is in the quarry just below Morgan's Station on the southeast side of Chester creek, about five miles from the city of Chester. The associate minerals are magnetite, hematite, green mica, quartz and a flesh-colored feldspar in which the crystals, about one-quarter of an inch in length, were observed. Two or three perfect crystals were found and a quantity of fragments. Mr. Dailey has subjected his find to the following examination:

"The best crystals were examined with the aid of a polariscope, and what appeared to be parallel extinction was observed, thus excluding the possibility of its being distorted garnet, which had been suggested, and it apparently confined the crystallization to practically tetragonal or orthorhombic; but upon looking up Monazite, which had been suggested, the angles of extinction were found to

very nearly approach right angles; thus the apparent parallel extinction of a monoclinic mineral was explained. Measurements (rough, to be sure, for the surfaces did not permit the reflection of a well-defined image) were made with the reflecting goniometer of two angles, one of which was an essential angle. For angle a w, which according to Dana is 39° 12′ 30′′, was found 39° and about 19′, and angle v v, which should be 73° 19′ 00′′, was found about 73° 30′.

A qualitative chemical analysis was thought necessary to insure and corroborate the above. The pulverized fragments were taken to dryness with hydrochloric acid, taken up with water and precipitated with oxalic acid. This precipitate gave upon ignition the peculiar red color of the cerium group. Another portion of powder upon fusion with white flux and solution in nitric acid gave with ammonium molybdate the characteristic reaction for phosphorus.

August 8.

MR. BENJAMIN SMITH LYMAN in the Chair.

Six persons present.

August 22.

MR. BENJAMIN SMITH LYMAN in the Chair.

Six persons present.

A paper entitled "New Species and Varieties of Mollusks from

Miami, Florida," by Henry A. Pilsbry, was presented for publication.

The death of W. D. Hartman, M.D., a correspondent, was announced.

August 29.

MR. BENJAMIN SMITH LYMAN in the Chair.

Nine persons present.

Confirmation of the Generic Characters of Ashmunella.—Dr. Pilsbry stated that living specimens of a new form of Ashmunella (A. thomsoniana porteræ Pils. & Ckll.) had been found recently by Miss Wilmatte Porter, one of Prof. Cockerell's pupils. It proves to be similar in anatomy to the type of the genus, thus confirming the generic diagnosis.

The following were ordered to be printed:
